

Civilian high temperature solar energy system

Overview

Through the Generation 3 CSP (Gen3 CSP) program, three teams have been selected to compete to build an integrated system that can efficiently receive solar heat and deliver it to a working fluid at greater than 700 °C temperature, while incorporating thermal energy storage. Department of Energy (DOE) announced \$72 million for new projects to advance high-temperature concentrating solar power (CSP) technologies. These systems utilize mirrors or lenses to focus sunlight onto a small area, creating high temperatures necessary to produce steam and drive. Solar power systems concentrate direct solar radiation turning it into a high-temperature energy source for the generation of electricity or to trigger chemical reactions. In this process, mirrors focus solar radiation onto receivers placed at the focal point, or in the focal line, of the system. This report looks at high-temperature solar thermal (HTST) technology, with the four main designs being considered: parabolic dish, parabolic trough, power tower, and linear Fresnel. First, a description of HTST technology is provided, and the commercialisation of HTST technology is examined.

Civilian high temperature solar energy system

Solar Energy at High Temperature

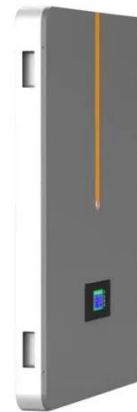

Solar power systems concentrate direct solar radiation turning it into a high-temperature energy source for the generation of electricity or to trigger chemical reactions.

High-Temperature Solar Power Systems

In contrast to the low-temperature solar devices, high-temperature solar systems achieve temperatures beyond 250 °C and can go up to 3000 °C or more by using concentrating collectors in the path of solar radiation.
