

# How thin can photovoltaic panels be made into wall panels

## Overview

---

The photovoltaic layers used in their construction are typically about 1 micron thick. To put that number into perspective, 1 micron is equal to one twenty-five thousandths of an inch. Thin-film solar cells (TFSC) are manufactured using a single or multiple layers of PV elements over a surface comprised of a variety of glass, plastic. These panels, which include materials like amorphous silicon (a-Si), Copper Indium Gallium Selenide (CIGS), and Cadmium Telluride (CdTe), are constructed by depositing layers of photovoltaic material onto a substrate. You'll find them primarily used in industrial and utility-scale solar projects because they require a lot of space to generate the same amount of electricity. The thickness of your solar panels is just as important but often overlooked. This measurement affects how you'll install them, how they'll perform, and how long they'll last. Unlike traditional silicon panels, which are rigid and bulky, thin-film panels are lightweight, flexible and easier to install on a wider range of surfaces.

### How thin can photovoltaic panels be made into wall panels

Thin-film solar panels are thin layers of photovoltaic (PV) materials that convert sunlight into electricity. These layers are usually only a few micrometers thick.
